

To add a signed 8-bit delta to a 16-bit value, we need to sign-extend the delta to a full 16 bits. The low byte can be added as normal, but the upper byte needs to be \$00 or \$ff based on the sign of the low byte.

```

; Precalculate the sign-extended high byte in .X
ldx #$00
lda delta
bpl :+
dex          ; decrement high byte to $ff for a negative delta
:

; Normal 16-bit addition
clc
adc value    ; .A still holds delta
sta value
txa          ; .X is the high byte
adc value+1
sta value+1

```

The following version uses only the accumulator, adding 2 bytes and 1 cycle:

```

; Standard low byte addition
clc
lda delta
adc value
sta value

; Sign extend the high byte
lda delta
and #$80    ; Extract the sign bit
beq :+      ; If zero, add #$00 (+ carry)
lda #$ff    ; Else, add $ff (+ carry)
:adc value+1
sta value+1

```
